House Price Prediction – Project Summary

The study found that the size of a house and the number of bathrooms are factors that affect house prices. Houses with space and better facilities usually cost more.

Two computer models were tested to predict house prices: Linear Regression and Random Forest Regressor. The Linear Regression model worked better with a score of around 0.65. This means it could explain 65% of why house prices vary.

One surprising thing we found was that houses with the same number of bedrooms can have very different prices. This suggests that things like the house's size, nearby infrastructure, and extra features may matter more than the number of bedrooms.

Based on what we found, real estate companies should use data to set house prices and focus on the features that make a house more valuable. This can help them price houses accurately and make better investment choices.
